Object-oriented languages such as Java and C# provide interfaces to support a restricted form of multiple inheritance. Existing low-level typed intermediate languages for object-oriented languages, however, either do not support interfaces or require non-standard interface implementations. This paper describes a typed intermediate language that can express the standard interface implementation strategies based on interface tables (itables). The language can faithfully model itables, the standard itable-based interface method invocation, and interface cast. The type system is sound and the type checking is decidable.
1 Introduction

Object-oriented languages that allow only single inheritance between classes, e.g., Java and C#, use interfaces to support a restricted form of multiple inheritance. Compilation from the source languages (Java and C#) to typed intermediate languages (Java bytecode [16] and .NET CIL [10]) preserves types, including interfaces, so that we can verify bytecode and CIL to guarantee type safety. Proof-Carrying Code [18] and Typed Assembly Language [17] push types to even lower-level typed intermediate languages to verify those representations. Existing lower-level typed intermediate languages for object-oriented languages, however, either do not support interfaces or require non-standard implementations.

This paper explains ECI (Encoding for Classes and Interfaces), a low-level typed intermediate language that supports both classes and interfaces. ECI is based on a language LILC that addresses only classes and single inheritance between classes [5]. ECI faithfully models the standard implementation techniques based on interface tables (itables), itable-based interface method invocation, and interface cast. It is the first typed intermediate language that is able to express these details.

Interfaces are difficult to support because of multiple inheritance. An interface may have different offsets in itables of different classes. Interface method invocation has to look up the itable at run time for the desired interface. ECI uses arrays and subclassing-bounded quantification to represent itables. Interface method invocation and interface cast are expressed as polymorphic functions in ECI. They can be inlined into ECI code compiled from source programs, and the result program can be optimized and type-checked because interface method invocation and interface cast are expressed entirely in ECI.

ECI is sound and its type checking is decidable. The proofs are in Appendix A. Appendix B formalizes a source language and a type-preserving translation from the source language to ECI. The source language is roughly Featherweight Java [13] with extensions of interfaces and arrays. Appendix C discusses how ECI may be extended to express advanced interface implementation techniques [14, 12, 7, 8, 9, 1].

2 Overview

We first give an informal overview of ECI. For clarity, this paper focuses on only core object-oriented features that are related to interfaces. Features such as generics, non-virtual methods, and null pointers are omitted.

Section 2.1 summarizes the key ideas of the base language LILC. We refer readers to the previous paper [5] for details of virtual method invocation, class cast, and arrays. Section 2.2 explains how ECI represents itables. Section 2.3 describes object layout. Section 2.4 addresses interface method invocation and interface cast.

2.1 Key Ideas of LILC

LILC is a low-level typed intermediate language for compiling object-oriented languages with classes. It is lower-level than bytecode and CIL because it describes implementation of virtual method invocation and type cast instead of treating them as primitives.

LILC differs from prior class and object encodings in that it preserves object-oriented notions such as class names and name-based subclassing, instead of compiling them away.

LILC uses an “exact” notion of classes. A class name in LILC represents only objects of exactly that class, not including objects of subclasses. Each class $C$ has a corresponding record type $R(C)$ that describes the object layout of $C$, including the vtable and the fields.

Objects can be coerced to or from records with appropriate record types, without runtime overhead. To create an object, we create a record and coerce it to an object. To fetch a field or invoke a method, we coerce the object to a record and then fetch the field or the method pointer from the record.

To represent an object of $C$ or $C$’s subclasses, LILC uses an existential type $\exists \alpha \ll C$. $\alpha$, read as “there exists $\alpha$ where $\alpha$ is a subclass of $C$, and the object has type $\alpha$”. The type variable $\alpha$ represents the object’s runtime type and the notation $\ll$ means subclassing. The type variable $\alpha$ has a subclassing bound $C$, which means that the runtime type of the object is a subclass of $C$. The subclassing bounds can only be class names or type variables that will be instantiated with class names. Subclassing-bounded quantification and the separation between name-based subclassing and structure-based subtyping make the type system decidable and expressive.
A source class name $C$ is then translated to an LIL type $\exists \alpha \ll C$. If $C$ is a subclass of class $B$, then $\exists \alpha \ll C$. $\alpha$ is a subtype of $\exists \alpha \ll B$. $\alpha$, which expresses inheritance—objects of $C$ or $C$’s subclasses can be used as objects of $B$ or $B$’s subclasses.

A class $C$ has a unique identifier (called tag) represented as $tag(C)$. The tag has type Tag($C$). If two tags are equal, the corresponding classes are the same.

### 2.2 Itable Representation

ECI extends the key ideas of LILC naturally to interfaces. ECI preserves interface names (ranged over by $I$, $J$, and $K$). Subclassing applies to interfaces: $C \ll I$ represents that class $C$ implements interface $I$, and $I \ll J$ represents that interface $I$ is a subinterface of interface $J$. Type variables can be bounded by and be instantiated with interface names. A source interface name $I$ is translated to an ECI type $\exists \alpha \ll I. \alpha$, meaning objects of classes that implement $I$. Interface $I$ has a unique identifier $tag(I)$, which has type Tag($I$).

The key data structure of itable-based interface implementation is the itable. In a common itable representation, a class includes in its itable an entry for each interface the class implements. Each interface entry contains two words: a tag and a pointer to the method table for the corresponding interface. The method table contains a function pointer for each method declared in the interface. The order of function pointers in the method table is the same in all itable entries that correspond to the same interface. This allows the compiler to use the same offset for a method in the method table of an interface, no matter in which class.

Figure 1 illustrates the itable of a class $C$ that implements two interfaces $J$ and $K$, each declaring an interface method $m_J$ and $m_K$ respectively. The itable has two entries, one for $J$ and the other for $K$. The method table for $J$ contains only one function pointer, the one for $m_J$. The method table pointer is given an ECI type $\text{Imty}(J, C)$, representing the method table for interface $J$ in class $C$’s itable. Method table type $\text{Imty}(J, C)$ can be coerced to/from a record type $\{m_J : \text{type-of-}m_J\}$, which contains a pointer to $m_J$’s implementation in $C$. Again, the coercions are runtime no-ops. The method table type refers to class $C$, indicating that the implementation of $m_J$ in the method table can be applied only to objects of $C$ or $C$’s subclasses. The class name $C$ is used in the “this” pointer type of $m_J$ ($\exists \alpha \ll C. \alpha$). The method table for $K$ is similar.

For an object whose runtime type is statically unknown, we cannot determine statically what interfaces its itable contains. Furthermore, the offsets of itable entries cannot be pre-determined because of multiple inheritance of interfaces. To invoke an interface method, we need to look up the itable at run time for the entry of the target interface.

To represent an itable that holds statically unknown interfaces with unknown ordering, ECI uses an array type, where each element corresponds to an itable entry. Each entry has two words, represented by a record type with two fields. ECI uses an existential type to abstract the interface to which each entry corresponds. An itable entry for class $C$ has type $\exists \alpha \gg C. \{\text{tag} : \text{Tag}(\alpha), \text{mtable} : \text{Imty}(\alpha, C)\}$. The type variable $\alpha$ indicates the interface to which the entry corresponds. $C$ implements the interface, therefore $C \ll \alpha$ and $\alpha$ is given the lower bound $C$. The body of the existential type is a record type with two fields labeled $\text{tag}$ and $\text{mtable}$, meaning the tag for the interface $\alpha$ and the method table respectively.

The itable entry array for class $\tau$ then has type array($\exists \alpha \gg \tau. \{\text{tag} : \text{Tag}(\alpha), \text{mtable} : \text{Imty}(\alpha, \tau)\}$), often abbreviated as $\text{ITY}(\tau)$. The itable of class $\tau$ has a record type $\{\text{length} : \text{int}, \text{table} : \text{ITY}(\tau)\}$. The field “length” records the number of itable entries (used by itable search). The field “table” is the entry array.

Interface method invocation searches the itable for the target interface by comparing the tag in each entry with the tag of the target interface. If an entry for the target interface is found, the method table in the entry is coerced to the record type that contains methods of the target interface. The desired interface
method can be fetched at a pre-determined offset from the record type.

Interface cast searches the itable similarly. Suppose the itable of an object with runtime type \( \tau \) contains an entry for interface \( I \). The subclassing bound in the itable entry type indicates that \( I \gg \tau \). Thus the object can be cast to \( I \).

### 2.3 Object Layout

Object layout—the organization of fields, methods, and runtime tags—in ECI is standard. Each object contains a pointer to the vtable and the fields. The vtable contains the tag, a pointer to the itable, and virtual method pointers. The rest of the paper uses records and pointers to records interchangeably. It should be clear from the context which one is being used.

Suppose a class \( C \) has fields \( f_1, \ldots, f_n \) of types \( s_1, \ldots, s_n \) respectively, and virtual methods \( m_1, \ldots, m_k \) of types \( t_1, \ldots, t_k \) (with explicit “this” pointer types) respectively. The layout of \( C \) is represented by the following record type:

\[
R(C) = \{vtable : \{tag : \text{Tag}(C),
\itable : \{length : \text{int}, table : \text{ITY}(C)\},
m_1 : t_1, \ldots, m_k : t_k\},
f_1 : s_1, \ldots, f_n : s_n\}
\]

The tag of \( C \) has type \( \text{Tag}(C) \). The itable type is explained in Section 2.2. Each virtual method in the vtable has an explicit “this” pointer as the first parameter. The “this” pointer has type \( \exists \alpha \ll C. \alpha \) to guarantee that only objects of \( C \) or \( C \)’s subclasses can be passed to the methods.

#### 2.3.1 Approximation of Object Layout

Layouts of objects whose runtime types are statically unknown can be approximated. Suppose an object has runtime type \( \alpha \) where \( \alpha \) is a subclass of the above class \( C \). The object contains at least fields and methods of \( C \). The object layout can be represented as follows:

\[
\text{ApproxR}(\alpha, C) = \{vtable : \{tag : \text{Tag}(\alpha),
\itable : \{length : \text{int}, table : \text{ITY}(\alpha)\},
m_1 : t_1, \ldots, m_k : t_k\},
f_1 : s_1, \ldots, f_n : s_n\}
\]

For objects with source type \( I \), the approximation record contains only the tag and the itable, no fields or methods. We cannot represent the entry for \( I \) in the itable because we cannot statically determine where the entry is located or what other entries the itable has.

\[
\text{ApproxR}(\alpha, I) = \{vtable : \{tag : \text{Tag}(\alpha), itable : \{length : \text{int}, table : \text{ITY}(\alpha)\}\}\}
\]

\( R \) and \( \text{ApproxR} \) are not type constructors in ECI, but macros used by the type checker. ECI can adopt other layout strategies by changing the macros.

Objects of type \( C \) (or \( \alpha \) where \( \alpha \ll C \)) are coerced to records of type \( R(C) \) (or \( \text{ApproxR}(\alpha, C) \)) before field fetch or virtual method invocation.

### 2.4 Interface Method Invocation and Interface Cast

We can now describe the itable lookup process during interface method invocation as the following polymorphic function in ECI. Note that without coercions (which are runtime no-ops anyway), it is exactly the standard implementation.

\[ fix \text{ILookup}\langle\alpha, \beta\rangle(t_{\alpha} : \text{Tag}(\alpha), \text{obj} : \beta) : \text{Imty}(\alpha, \beta) \]

1. `itable : \{length : \text{int}, table : ITY(\beta)\} = c2r(obj).vtable.itable in \}/itable`  
2. `arr : ITY(\beta) = itable.table in \}/get entry array`  
3. `len : \text{int} = itable.length in \}/get itable length`  
4. `\text{loop}[\alpha, \beta](t_{\alpha}, \text{obj}, \text{arr}, 0, \text{len})` \}/start search

\[ fix \text{loop}\langle\alpha, \beta\rangle \]

5. `(i \geq \text{len}) \text{then} \text{error[Imty}(\alpha, \beta)] \text{else} \}/not found`  
6. `entryi : \exists \gamma \gg \beta. \{\text{tag} : \text{Tag}(\gamma), \text{mtable} : \text{Imty}(\gamma, \beta)\} = arr[i] in \}/\text{ith entry}`  
7. `(\gamma', \text{entryi}') = \text{open}(\text{entryi}) in \}/\gamma' \gg \beta, \text{entryi}' : \{\text{tag} : \text{Tag}(\gamma'), \text{mtable} : \text{Imty}(\gamma', \beta)\}`  
8. `\text{ifEqTagImty[Imty}(\gamma', \beta)](\text{entryi}'.\text{tag}, t_{\alpha}) \text{then} \text{entryi}'.\text{mtable} \text{else} \}/\gamma' = \alpha`  
9. `\text{loop}[\alpha, \beta](t_{\alpha}, \text{obj}, \text{arr}, i + 1, \text{len})` \}/next iteration

The function `ILookup` takes two type parameters—the target interface `\alpha` and the runtime type `\beta` of the object, and two value parameters—the tag of the target interface and the object. `ILookup` returns the method table for the target interface `\alpha` in class `\beta` if `\alpha` is found. Otherwise an error occurs.

Step 1) coerces `\text{obj}` to a record `c2r(obj)` and fetches the vtable and then the itable from the record. Step 2) gets the entry array from the itable. Step 3) gets the length of the itable and step 4) calls `\text{loop}` to iterate over the entry array.

Function `\text{loop}` is a polymorphic function with the same type parameters as `ILookup`. It has three additional parameters: `\text{arr}` for the interface entry array, `i` for the index of the current entry, and `\text{len}` for the length of the itable. Step 5) tests if the search reaches the end of the itable. If so, an error is returned. Otherwise, step 6) fetches the `\text{ith entry from the entry array. Step 7) opens the entry and introduces a fresh type variable `\gamma'` for the interface corresponding to the entry. Step 8) compares the tag in the entry `(entryi'.\text{tag} with type Tag(\gamma')) with the target interface's tag (t_{\alpha} with type Tag(\alpha)). If the tags are the same, then `\gamma' = \alpha`. The method table in the entry (with type Imty(\gamma', \beta)) is returned as a value of type Imty(\alpha, \beta). Otherwise, step 9) calls `\text{loop}` for the next iteration.

The following example demonstrates interface method invocation—how to invoke the method `m_J` on an object `\text{obj}` with source type `J` in Figure 1:

1. `(\beta, \text{obj}') = \text{open}(\text{obj})` \}/open object. `\text{obj} : \exists \alpha \ll J, \alpha, \text{obj}' : \beta`  
2. `\text{mtable} = ILookup[J, \beta](\text{tag}(J), \text{obj}')` \}/lookup itable. `\text{mtable} : \text{Imty}(J, \beta)`  
3. `r = im2r(\text{mtable})` \}/coerce mtable. `r : \{m_J : \text{type_of}_m_J\}`  
4. `m = r.m_J` \}/fetch method. `m : \text{type}_m_J`  
5. `m(\text{obj}')` \}/invoke the method.

The source type `J` is translated to ECI type `\exists \alpha \ll J, \alpha`, the type of `\text{obj}`. Step 1) opens the existential type and introduces a fresh type variable `\beta` for the runtime type of `\text{obj}`. The opened object `\text{obj}'` has type `\beta`. Step 2) calls `ILookup` to search for the interface `J`. The return value is the method table for `J` in class `\beta`, which has type `\text{Imty}(J, \beta)`. Step 3) then coerces the method table to a record `r` that lists all `J`'s methods. Step 4) fetches the method `m_J` from `r` and step 5) calls the method with `\text{obj}'` as the “this” pointer.

ECI can express without difficulties optimizations of itable lookup such as caching and move-to-front. The cached entry can have the same type as the itable entries. The move-to-front strategy can also be expressed because ECI's array representation of itables does not care about the orders of itable entries.

### 2.4.1 Interface Cast

Interface downward cast may cast an object of an arbitrary type to an interface, by searching at run time for an itable entry that corresponds to the target interface. The downward cast is represented by a polymorphic function similar to `ILookup`.  

---

4
It calls castLoop to search the itable for the entry for α. If found, step 8 coerces the object (with type β) to the return type ∃δ ≪ α. δ because β has a superinterface γ' that equals α (thus β ≪ α).

3 Syntax of ECI

This section explains the syntax of ECI. We underline new interface-related constructs to distinguish them from those introduced in the base language LILc.

3.1 Kinds and Types

| (kind) | κ ::= Ωc | Ω |
| (type) | τ ::= int | α | array(τ) | (τ1, ..., τn) → τ | {t[τ]1 : τ1, ..., t[τ]n : τn} |
|        | | C | Tag(τ) | ∀α ≪ τ. τ' | ∃α ≪ τ. τ' | {t[τ]1 : τ1, ..., t[τ]n : τn} |
| (lbl ann) | φ ::= I | M |
| (tvars) | tvs ::= • | α ≪ τ, tvs |

Figure 2: Kinds and Types

Kind Ωc classifies class/interface names and type variables that will be instantiated with class/interface names. The well-formedness rules of types use this kind to guarantee that certain type constructors (e.g. Tag) are applied to only class/interface names and type variables. Kind Ω classifies all types and Ωc is a subkind of Ω.

Standard types include integer type, type variable “α”, array type “array(τ)”, function type “(τ1, ..., τn) → τ”, and record type “{t[τ]1 : τ1, ..., t[τ]n : τn}”. In a record type, each field label is annotated with either “I” or “M”, representing immutable and mutable respectively. “I” is often omitted. LILc introduced class name “C”, tag type “Tag(τ)”, subclassing-bounded quantified types “∀α ≪ τ. τ’” and “∃α ≪ τ. τ’”, and exact record type “{t[τ]1 : τ1, ..., t[τ]n : τn}” (which represents records that have and only have the specified fields). R(C) is an exact record type to rule out extra fields.

New types for interfaces include interface names “I”, interface method table type “Imty(τ1, τ2)”, and existential type “∃α ≪ τ. τ’” which specifies a lower subclassing bound τ for its type variable α. The new existential type is used in itable types, as shown in Section 2.2.
3.2 Values and Expressions

\[
\begin{align*}
\text{(value)} \quad v & ::= n \mid \ell \mid C(v) \mid \text{tag}(C) \mid \text{tag}(I) \mid r2im[I,C](v) \\
& \quad \mid \text{pack } \tau \text{ as } \alpha \ll \tau_u \text{ in } (v : \tau') \\
\text{(hvalue)} \quad hv & ::= \{l_i = v_i\}_{i=1}^n \mid [v_0, \ldots, v_{n-1}]'' \mid \text{fix } g(tvs)(x_1 : \tau_1, \ldots, x_n : \tau_n) : \tau = e_m \\
\text{(expr)} \quad e & ::= x \mid n \mid \ell \mid \text{tag}(C) \mid \text{tag}(I) \mid C(e) \mid e2r(e) \\
& \quad \mid r2im[\tau_1, \tau_2](e) \mid im2r(e) \mid \text{error}[\tau] \\
& \quad \mid \text{new}[\tau]_1[l_i = e_i]_{i=1}^n \mid e.I \mid e_1.l_i := e_2 \text{ in } e_3 \\
& \quad \mid \text{new}[e_0, \ldots, e_{n-1}]'' \mid e_1[e_2] \mid e_1[e_2] := e_3 \text{ in } e_4 \\
& \quad \mid x : \tau = e_1 \text{ in } e_2 \mid x := e_1 \text{ in } e_2 \\
& \quad \mid e[\tau_1, \ldots, \tau_m](e_1, \ldots, e_n) \mid (\alpha, x) = \text{open}(e_1) \text{ in } e_2 \\
& \quad \mid \text{pack } \tau \text{ as } \alpha \ll \tau_u \text{ in } (e : \tau') \\
& \quad \mid \text{pack } \tau \text{ as } \alpha \gg \tau_u \text{ in } (e : \tau') \\
& \quad \mid \text{ifParent}(e) \text{ then bind } (\alpha, x) \text{ in } e_1 \text{ else } e_2 \\
& \quad \mid \text{ifEqTag}(e_{11}, e_{12}) \text{ then } e_1 \text{ else } e_2
\end{align*}
\]

Figure 3: Values and Expressions

Word-sized values include integer “n”, heap label “\ell”, object of class C “tag(C)” (coerced from record v), tag of class C “tag(C)”, and packed word-sized value “pack \tau as \alpha \ll \tau_u in (v : \tau’)”. The packed value has type \exists \alpha \ll \tau_u. \tau’.

New word-sized values include tag of interface I “tag(I)”, method table for interface I in class C “r2im[I,C](v)” (coerced from a record v containing C’s implementations of methods in I), and packed values with lower bounds “pack \tau as \alpha \gg \tau_u in (v : \tau’)”. The value r2im[I,C](v) has type Inty(I,C).

Heap values include record “\{l_i = v_i\}_{i=1}^n”, array “[v_0, \ldots, v_{n-1}]’”, and function “fix g(tvs)(x_1 : \tau_1, \ldots, x_n : \tau_n) : \tau = e_m”. Arrays are annotated with their element types. Functions may be polymorphic. The return type is also specified in each function.

Besides values, ECI expressions include variable “x”, coercing a record e (with type R(C)) to a C object “C(e)”, coercing an object e to a record “e2r(e)”, runtime error expression “error[\tau]” (an expression of type \tau is expected in normal execution), record creation “new[\tau]_1[l_i = e_i]_{i=1}^n”, field access “e.I”, field assignment “e_1.l_i := e_2 in e_3”, array creation “new[e_0, \ldots, e_{n-1}]’”, array subscript “e_1[e_2]”, array element assignment “e_1[e_2] := e_3 in e_4”, let binding “x : \tau = e_1 in e_2” (\tau specifies x’s type), variable assignment “x := e_1 in e_2”, function call “e[\tau_1, \ldots, \tau_m](e_1, \ldots, e_n)”, open expression “(\alpha, x) = \text{open}(e_1) in e_2”, pack expression “pack \tau as \alpha \ll \tau_u in (e : \tau’)”, fetching-parent-tag expression “ifParent(e) then bind (\alpha, x) in e_1 else e_2”, and tag comparison expression “ifEqTag(e_{11}, e_{12}) then e_1 else e_2”. The “ifParent” expression is used in class downward casts [5]. If tag e has a parent tag, then the “ifParent” expression binds the superclass parent tag indicates to a fresh type variable \alpha and the parent tag to x and evaluates e_1. Otherwise the control transfers to e_2. The desired result type \tau is annotated to simplify type checking. The “ifEqTag” expression compares two tags e_{11} and e_{12}. If they are equal, the types identified by the tags are the same. The true branch e_1 is type-checked assuming that the two types are the same.

Two new expressions in ECI describe coercions between interface method tables and records. Expression r2im[\tau_1, \tau_2](e) coerces a record e containing methods for interface \tau_1 in class \tau_2 to a method table (with type Inty(\tau_1, \tau_2)). Expression im2r(e) coerces a method table e to a record.

To introduce values of existential types with lower subclassing bounds, a second pack expression “pack \tau as \alpha \gg \tau_u in (e : \tau’)” coerces an expression e to type \exists \alpha \gg \tau_u. \tau’, by hiding type \tau (where \tau \gg \tau_u) with type variable \alpha. The packed values can be unpacked by the existing “open” expression.
3.2.1 Declarations and Programs

Field declaration “\( f : \tau \)” introduces a field named \( f \) with type \( \tau \). Method declaration “\( m : \forall \ tvs \ (\tau_1, \ldots, \tau_n) \rightarrow \tau \)” specifies a method named \( m \) with type \( \forall \ tvs \ (\tau_1, \ldots, \tau_n) \rightarrow \tau \). Only the method signature is declared here. Method implementations are represented as functions on the heap. Heap “\( H \)” maps labels to heap values. Variable-value mapping “\( V \)” maps variables to word-sized values.

A class declaration \( C : B, \overline{T} \{ \text{field}, \text{method} \} \) declares a class name \( C \) with superclass \( B \), all its superinterfaces \( \overline{T} \), and all its fields and methods including those from the superclasses. The notation \( \overline{T} \) means a sequence of items in \( \rho \).

An interface declaration “\( I : \overline{J} \{ \text{method} \} \)” specifies an interface name \( I \), all its super interfaces \( \overline{J} \), and declarations of all the methods in the interface and its superinterfaces \( \text{method} \).

A program has a set of class declarations, a heap \( H \), a variable-value mapping \( V \), and a main expression.

4 ECI Semantics

This section explains the semantics of ECI.

ECI maintains a declaration table \( \Theta \) that maps class and interface names to their declarations. A kind environment \( \Delta \) tracks type variables in scope and their bounds. Each entry in \( \Delta \) introduces a new type variable, and an upper or lower bound of the type variable. The bound is a class name, an interface name, or another type variable introduced previously in \( \Delta \). A heap environment \( \Sigma \) maps heap labels to types. A type environment \( \Gamma \) maps variables to types. Substitution \( \tau/\alpha \) means replacing \( \alpha \) with \( \tau \).

4.1 Types

The kinding judgment \( \Theta; \Delta \vdash \tau : \kappa \) means that, under environments \( \Theta \) and \( \Delta \), type \( \tau \) has kind \( \kappa \). Figure 5 shows the kinding rules. Topc is a special class name similar to the Object class. Any other class name is a subclass of Topc.
All type variables have kind $\Omega$. The tag constructor can be applied only to types with kind $\Omega$. Non-standard kinding rules are those related to $\Omega_c$, the kind that classifies class and interface names. 

4.2 Expressions

The typing judgment $\Theta; \Delta; \Sigma; \Gamma \vdash e : \tau$ means that, under environments $\Theta$, $\Delta$, $\Sigma$ and $\Gamma$, expression $e$ has type $\tau$. Figure 8 lists the expression typing rules. Only records of type $\mathbb{R}(C)$ can be coerced to objects of $C$ (rule object). Coercing an object of $C$ to a record results in a record of type $\mathbb{R}(C)$ (rule c2r_e). Coercing an object of $\alpha$ to a record results in a record of type $\text{ApproxR}(\alpha, C)$ if $\alpha \ll C$ (rule c2r_tv).

$\mathbb{R}_I$ is a macro used by the type checker to represent record types that correspond to method tables, similar to $R$ and $\text{ApproxR}$. Suppose interface $I$ declares methods $m_1, \ldots, m_k$ of type $\tau_1, \ldots, \tau_k$ respectively. $\mathbb{R}_I(I, \tau)$ is defined as $\mathbb{R}_I(I, \tau) = \{ m_1 : \tau_1, \ldots, m_k : \tau_k \}$ where $\tau_i$ refers to $\tau$ in the “this” pointer types.

Expression $\mathbb{R}_I(I, \tau)$ coerces a record of type $\mathbb{R}_I(I, \tau)$ to a method table type $\text{Imty}(I, \tau)$ (rule r2im). Expression $\mathbb{R}_I(I, \tau)$ coerces a method table $e$ with type $\text{Imty}(I, \tau)$ to a record type $\mathbb{R}_I(I, \tau)$ (rule r2im).
\[ \Theta; \Delta; \Sigma; \Gamma \vdash x : \Gamma(x) \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash \ell : \Sigma(\ell) \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash e : C \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash \text{ifTag_neq}(e_1, e_2) \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash \text{ifTag_tv}(e_1, e_2) \]

Figure 8: Expression Typing Rules
can be a type variable or a class name (rule \texttt{im2r}).

Rule \texttt{call} requires that in a call expression \texttt{"e[τ_1,...,τ_n](e_1,...,e_n)"}, the (polymorphic) function \texttt{e} have a function type \(\forall tv\langle s_1,...,s_n \rangle \rightarrow s\). The type arguments \(τ_1,...,τ_n\) must satisfy the constraints \(tv\) specifies. The value arguments \(e_1,...,e_n\) have types \(s_1,...,s_n\) respectively, after the type variables in \(tv\) are replaced with \(τ_1,...,τ_n\).

Rule \texttt{open} checks elimination of existential types with upper bounds. It is standard except for the sublassing bounds. Rule \texttt{pack} introduces existential types with upper bounds. It checks that the hidden type \(τ\) is a subclass of the specified bound \(τ_u\).

ECI has additional typing rules for the open and pack expressions that eliminate and introduce existential types with upper bounds respectively (rules \texttt{open} and \texttt{pack}.

Rule \texttt{ifParent} says that in \texttt{"ifParent\(e\)\(\)\(\)\(\)\(\)\(\)\(\)\(\)}\(\)\(\texttt{α, x}\) in \(e_1\) else \(e_2\)”, tag \(e\) has type \(\texttt{Tag}(\(τ\)'\)) for some type \(\tau\). If \(e\) has a parent tag, a new type variable \(\alpha\) is introduced for the superclass of \(\tau\)' and a new value variable \(x\) (of type \texttt{Tag}(\(\alpha\))) is introduced for the parent tag. Both branches \(e_1\) and \(e_2\) need to have the annotated type \(\tau\).

The last three rules check tag comparison expressions. In \texttt{"ifEqTag\(e_1, e_2\)\(\)\(\)\(\)\(\)\(\)}\(\)\(\texttt{α, x}\) in \(e_1\) else \(e_2\)”, if both \(e_{\text{\small{tl}}}\) and \(e_{\text{\small{tr}}}\) are tags for concrete class names, the type checker only checks the branch to be taken (rule \texttt{ifTag_eq}, \texttt{ifTag_neq}). Otherwise (rule \texttt{ifTag_tv}), the first tag \(e_{\text{\small{tl}}}\) must have type \texttt{Tag}(\(\gamma\)) for some type variable \(\gamma\). The second tag \(e_{\text{\small{tr}}}\) can be a tag for type \(\tau\), either a class name or a type variable introduced before \(\gamma\). The checker uses \(\gamma = \tau\) to refine the type of the true branch \(e_1\), because \(\gamma = \tau\) must hold if the true branch is taken. The false branch has no type refinement.

Figure 9 lists the typing rules for heap values. The judgment \(Θ; Σ \vDash hv : τ\) means that under the environments \(Θ\) and \(Σ\), heap value \(hv\) has type \(τ\).

\[
\begin{align*}
Θ; •; Σ; • \vDash v_i : τ & \forall 0 \leq i \leq n-1 \quad \text{hv_array} \\
Θ; Σ \vDash \langle v_0, \ldots, v_{n-1} \rangle : \text{array}(τ) \\
Θ; Σ \vDash \{ I_1 = v_1 \}_{i=1}^{n} : \{< i \sigma_1 : τ_1 >_{i=1}^{n} \} \quad \text{hv_record} \\
Θ; Σ \vDash \tau_f = \forall tv\langle τ_1, \ldots, τ_n \rangle \rightarrow τ \\
Θ; Σ \vDash \{ I_1 = τ_1 \}_{i=1}^{n} : \{< i \sigma_1 : τ_1 >_{i=1}^{n} \} \quad \text{hv_fun} \\
Θ; Σ \vDash g(tv) ; x_1 : τ_1, \ldots, x_n : τ_n \vDash e_m : τ \\
\end{align*}
\]

Figure 9: Heap Value Typing Rules

4.3 Interface Declaration

A well-formed interface contains all the methods of its super interfaces, with same types. The superinterfaces must be declared before the subinterface.

| \(\forall 1 \leq i \leq n, I_i\) declared before \(I\) | \(Θ \vdash I : \{\ldots\} \) |
| \(\forall\) methods \(m\) in \(I_i, m \in m_1, \ldots, m_j\) | \(Θ \vdash I : I_1, \ldots, I_n\{m_1 : t_1, \ldots, m_j : t_j\}\) |

4.4 Class Declarations and Programs

Figure 10 shows the well-formedness rules for class declarations. A well-formed class contains all the members inherited from its parent class and superinterfaces, which is solely an implementation strategy to simplify looking up members. The parent class and the superinterfaces must be declared before the child class.

Figure 11 lists the well-formedness rule for programs. A program \((Θ; H; V; e)\) is well-formed with respect to a heap environment if all its declarations in \(Θ\) are well-formed (including interface declarations), the heap \(H\) respects the heap environment, the variable-value binding \(V\) is well-formed and the main expression \(e\) is well-typed (see Figure 11). The main expression \(e\) has no free type variables, and refers only to labels in \(H\) and variables in \(V\).
4.5 Dynamic Semantics

Figure 12 shows the evaluation rules for the ECI expressions. The expressions in the first column evaluate one step to the corresponding ones in the second column, if the side conditions in the third column hold. Judgment $P \rightarrow P'$ means that $P$ steps to $P'$.

Expressions $C(v)$ and $c2r(v)$ coerce between objects and records. Expressions $r2im[\tau_1, \tau_2](v)$ and $im2r(v)$ coerce between concrete and abstract interface method tables. “ifParent” $(tag(C))$ then bind $(\alpha, x)$ in $e_1$ else $e_2$” steps to $e_1$ with $\alpha$ replaced with $B$ and $x$ assigned $tag(B)$, if $C$ extends some class $B$. Otherwise it steps to $e_2$. Expression “ifEqTag” $(tag(C_1), tag(C_2))$ then $e_1$ else $e_2$” steps to $e_1$ if $C_1 = C_2$, and to $e_2$ otherwise. The evaluation of an error expression “error[$\tau$]” infinitely loops.

We have proved that ECI has the following properties:

**Theorem 1 (Preservation)** If $\Sigma \vdash P : \tau$ and $P \rightarrow P'$, then $\exists \Sigma' \text{ such that } \Sigma' \vdash P' : \tau$.

**Theorem 2 (Progress)** If $\Sigma \vdash P : \tau$, then the main expression in $P$ is a value, or $\exists P''$ such that $P \rightarrow P''$.

**Theorem 3 (Decidability)** It is decidable whether $\Theta; \Delta; \Sigma; \Gamma \vdash e : \tau$ holds.

Proofs can be found in Appendix A.

5 Related Work

League et al. proposed a typed intermediate language JFlint for compiling Java-like languages [15]. JFlint uses existential quantification over row variables for object encodings. There are two approaches to support interfaces. The first approach uses unordered records for itable entries, which does not model itable search. The second approach pairs a specialized itable with an object when casting the object to an interface. The specialized itable contains only information of the target interface. The second approach requires non-standard implementation: upcasting is no longer free.

Chen et al. proposed a model based on guarded recursive datatypes that supports multiple inheritance between classes [4]. The model preserves class names. Each method invocation is associated with a sequence of class names, for identifying methods. This approach encodes objects with functions, which differs from
the standard implementation of objects as records. As a result, object layouts, including vtables and itables, cannot be addressed.

SpecialJ compiles Java to Proof-Carrying Code [6]. The target language preserves class and interface names, but the paper [6] didn’t discuss how the target type system addresses itable or interface implementation.

6 Conclusion

This paper describes a typed intermediate language that supports interfaces, a restricted form of multiple inheritance. The language models itables with array types and subclassing-bounded quantification. It faithfully models the standard itable-based implementation of interface method invocation and interface cast.

A Decidability and Soundness Proofs of ECI

This section presents the proofs for decidability and soundness of ECI. We describe only important lemmas and proof sketches.

A.1 Supporting Lemmas

**Lemma 4 Weakening of kind environment:**

Suppose $\alpha \not\in \text{domain}(\Delta)$, and $\Delta' = \Delta, \alpha \ll u$ or $\Delta' = \Delta, \alpha \gg u$:

1. If $\Theta; \Delta \vdash \tau : \kappa$, then $\Theta; \Delta' \vdash \tau : \kappa$.
2. If $\Theta; \Delta \vdash \tau_1 \ll \tau_2$, then $\Theta; \Delta' \vdash \tau_1 \ll \tau_2$.
3. If $\Theta; \Delta \vdash \tau_1 \leq \tau_2$, then $\Theta; \Delta' \vdash \tau_1 \leq \tau_2$.
Proof: by induction on kinding, subclassing and subtyping rules.

Lemma 5 Weakening of heap environment. If \( \Theta; \Delta; \Sigma; \Gamma \vdash e : \tau \) and \( \Sigma' = \Sigma, \ell : \tau \) where \( \ell \) is a fresh label, then \( \Theta; \Delta; \Sigma'; \Gamma \vdash e : \tau \).

Proof: by induction on expression typing rules.

Lemma 6 Weakening of type environment. If \( \Theta; \Delta; \Sigma; \Gamma \vdash e : \tau \) and \( \Sigma'' = \Sigma \), \( \ell : \tau \) where \( \ell \) is a fresh label, then \( \Theta; \Delta; \Sigma''; \Gamma \vdash e : \tau \).

Proof: by induction on expression typing rules.

Lemma 7 Type substitution preserves kinding, subclassing and subtyping.

Suppose \( \Delta = \Delta_1, \eta \ll \sigma, \Delta_2 \) and \( \Theta; \Delta_1 \vdash s \ll \sigma \) (or \( \Delta = \Delta_1, \eta \gg \sigma, \Delta_2 \) and \( \Theta; \Delta_1 \vdash \sigma \ll s \)), and \( \delta = s/\eta \) and \( \Delta' = \Delta_1, \Delta_2[\delta] \).

- If \( \Theta; \Delta \vdash \sigma : \kappa \), then \( \Theta; \Delta' \vdash \sigma[\delta] : \kappa \).
- If \( \Theta; \Delta \vdash \tau_1 \ll \tau_2 \), then \( \Theta; \Delta' \vdash \tau_1[\delta] \ll \tau_2[\delta] \).
- If \( \Theta; \Delta \vdash \tau_1 \leq \tau_2 \), then \( \Theta; \Delta' \vdash \tau_1[\delta] \leq \tau_2[\delta] \).

Proof: by induction on kinding, subclassing and subtyping rules.

A.1.1 Subclassing

Definition 8 Class/interface and type variable lifting. We define an operation \( \tau \uparrow \Delta \) to compute the least super class name for type \( \tau \) in environment \( \Delta \). This is used in minimal typing.

\[
\begin{align*}
C \uparrow \Delta & = C \\
I \uparrow \Delta & = \text{Topc} \\
\alpha \uparrow \Delta & = \begin{cases} 
\tau \uparrow \Delta & \alpha \ll \tau \in \Delta \\
\text{Topc} & \alpha \gg \tau \in \Delta 
\end{cases}
\end{align*}
\]

By definition, \( \tau \uparrow \Delta \) is a class name. The process of computing \( \tau \uparrow \Delta \) always terminates because there is no loop in \( \Delta \). Also it has the following properties:

Lemma 9 Properties of class/interface and type variable lifting

1. \( \Theta; \Delta \vdash \gamma \ll \gamma \uparrow \Delta \).
2. If \( \Theta; \Delta \vdash \tau_1 \ll \tau_2 \), then \( \Theta; \Delta \vdash \tau_1 \uparrow \Delta \ll \tau_2 \uparrow \Delta \).

Proof: 1: by induction on depth where depth is defined as: depth(\( \alpha \)) = depth(\( \tau \)) + 1 if \( \alpha \ll \tau \in \Delta \), and for all other cases, depth(\( \tau \)) = 0.
2: by induction on subclassing rules.

A.1.2 Subtyping

We define type lifting and type lowering in Figure 13. They are also used in minimal typing.

\( \tau \uparrow \Delta \) is defined to be the least super type of \( \tau \) under environment \( \Delta \) that contains no free occurrence of \( \alpha \). Similarly, \( \tau \downarrow \Delta \) is defined to be the greatest subtype of \( \tau \) under environment \( \Delta \) that contains no free occurrence of \( \alpha \). Note that \( \alpha \) appears as the last entry in \( \Delta \). The definitions of lifting and lowering are mutually recursive.

Type lifting and lowering have the following properties:

Lemma 11 Properties of Type Lifting.

Let \( \Delta' = \Delta, \alpha \ll u_\alpha \) or \( \Delta' = \Delta, \alpha \gg u_\alpha \).
Definition 10  Type lifting and lowering. Suppose $\Delta = \Delta_1$, $P(\alpha) = \alpha \ll u_\alpha$ or $P(\alpha) = \alpha \gg u_\alpha$:

$$
\begin{align*}
(\tau) &\uparrow^\Delta_{\alpha} = \tau & \text{if } \alpha \notin \text{free}(\tau) \\
(\exists \beta \ll u. \tau) &\uparrow^\Delta_{\alpha} = (\exists \beta \ll u. \tau') & \text{if } u \neq \alpha \text{ and } \tau' = (\tau) \uparrow^\alpha_{\Delta_1, \beta \ll \text{Topc}, P(\alpha)} \\
(\exists \beta \ll \alpha. \tau) &\uparrow^\Delta_{\alpha} = (\exists \beta \ll u_\alpha. \tau') & P(\alpha) = \alpha \ll u_\alpha \text{ and } \tau' = (\tau) \uparrow^\alpha_{\Delta_1, \beta \ll \text{Topc}, P(\alpha)} \\
(\exists \beta \gg u. \tau) &\uparrow^\Delta_{\alpha} = (\exists \beta \gg u. \tau') & \text{if } u \neq \alpha \text{ and } \tau' = (\tau) \uparrow^\alpha_{\Delta_1, \beta \ll \text{Topc}, P(\alpha)} \\
(\forall \beta \ll \alpha. \tau) &\uparrow^\Delta_{\alpha} = (\forall \beta \ll u_\alpha. \tau') & P(\alpha) = \alpha \gg u_\alpha \text{ and } \tau' = (\tau) \uparrow^\alpha_{\Delta_1, \beta \ll \text{Topc}, P(\alpha)} \\
(\forall \beta \ll \alpha. \tau) &\uparrow^\Delta_{\alpha} = \forall \beta < u_\alpha. \tau' & \text{if } u \neq \alpha \text{ and } \tau' = (\tau) \uparrow^\alpha_{\Delta_1, \beta \ll \text{Topc}, P(\alpha)} \\
((\tau_1, \ldots, \tau_n) \rightarrow \tau) &\uparrow^\Delta_{\alpha} = (\tau'_1, \ldots, \tau'_n) \rightarrow \tau' & \tau'_i = (\tau_i) \downarrow^\alpha_{\Delta_1, \beta \ll \text{Topc}, P(\alpha)} \text{ and } \tau' = (\tau) \uparrow^\alpha_{\Delta_1, \beta \ll \text{Topc}, P(\alpha)} \\
\{\phi_i : \tau_i\}_{i=1}^n &\uparrow^\Delta_{\alpha} = \{\phi_i : \tau'_i\}_{i=1}^m & m = \max \left\{ \begin{array}{ll} j & \forall i \leq j \text{ if } \phi_i = M \text{ then } \alpha \notin \text{free}(\tau_i) \\ \text{otherwise} & \exists (\tau_i) \downarrow^\alpha_{\Delta_1, \beta \ll \text{Topc}, P(\alpha)} \end{array} \right\} \\
\langle \{\phi_i : \tau_i\}_{i=1}^n \rangle &\uparrow^\Delta_{\alpha} = \langle \{\phi_i : \tau'_i\}_{i=1}^n \rangle & \forall \tau_i = M \forall 1 \leq i \leq n \text{ if } \phi_i = M \text{ then } \alpha \notin \text{free}(\tau_i) \\
\end{align*}
$$

Figure 13: Type Lifting and Lowering
Lemma 12 Properties of Approximation

1. If \( \exists s \) such that \( \alpha \notin \text{free}(s) \) and \( \Theta; \Delta' \vdash \tau \leq s \), then \( (\tau) \uparrow_{\Delta'}^a \) exists, and \( \Theta; \Delta' \vdash (\tau) \uparrow_{\Delta'}^a \leq s \), and \( \forall t \) such that \( \Theta; \Delta' \vdash \tau \leq t \) and \( \alpha \notin \text{free}(t) \), then \( \Theta; \Delta \vdash (\tau) \uparrow_{\Delta}^a \leq t \).

2. If \( \Theta; \Delta' \vdash s \leq \tau \) and \( \alpha \notin \text{free}(s) \), then \( (\tau) \downarrow_{\Delta'}^a \), exists and \( \Theta; \Delta' \vdash (\tau) \downarrow_{\Delta'}^a \leq \tau \), and \( \forall t \) such that \( \Theta; \Delta' \vdash t \leq \tau \) and \( \alpha \notin \text{free}(t) \), then \( \Theta; \Delta \vdash (\tau) \downarrow_{\Delta}^a \leq t \).

3. If \( \Theta; \Delta' \vdash \tau_1 \leq \tau_2 \), then \( \Theta; \Delta \vdash (\tau_1) \uparrow_{\Delta'}^a \leq (\tau_2) \uparrow_{\Delta'}^a \).

Proof:
1, 2: by mutual induction on the definition of lifting and lowering.
3: let \( T_1 = (\tau_1) \uparrow_{\Delta'}^a \), and \( T_2 = (\tau_2) \uparrow_{\Delta'}^a \). By \( T \vdash \Delta' \vdash \tau_1 \leq \tau_2 \). By transitivity of subtyping \( \Theta; \Delta' \vdash \tau_1 \leq \tau_2 \). By 1 and \( \alpha \notin \text{free}(T_2) \), \( \Theta; \Delta \vdash T_1 \leq T_2 \).

Lemma 13 Subclassing is decidable.

A.2 Decidability of Type Checking

Lemma 14 The algorithmic subtyping rules are sound. If \( \Theta; \Delta \vdash T_1 \leq T_2 \), then \( \Theta; \Delta \vdash T_1 \leq T_2 \).

Proof: by induction on the algorithmic subtyping rules.

Lemma 15 The algorithmic subtyping is transitive. If \( \Theta; \Delta \vdash \Delta' \vdash \Delta'' \vdash T_2 \) and \( \Theta; \Delta' \vdash T_1 \leq T_2 \), then \( \Theta; \Delta \vdash T_1 \leq T_2 \).

Proof: by induction on the sum of the sizes of the left derivation \( \Theta; \Delta \vdash T_1 \leq T_2 \) and the right derivation \( \Theta; \Delta \vdash T_2 \leq T_3 \).

Lemma 16 The algorithmic subtyping is complete. If \( \Theta; \Delta \vdash T_1 \leq T_2 \), then \( \Theta; \Delta \vdash T_1 \leq T_2 \).

Proof: by induction on the subtyping rules. The transitivity case is proven by Lemma 15.

Definition 17 size of types.

\[
\begin{align*}
\text{size}(\forall \alpha \ll \tau, \tau') &= \text{size}(\tau') + 1 \\
\text{size}(\exists \alpha \ll \tau, \tau') &= \text{size}(\tau') + 1 \\
\text{size}(\exists \alpha \gg \tau, \tau') &= \text{size}(\tau') + 1 \\
\text{size}(\tau_1, \ldots, \tau_n \rightarrow \tau) &= \sum_{i=1}^{n} \text{size}(\tau_i) + \text{size}(\tau) + 1 \\
\text{size}(\llbracket l_0^0 : \tau_1, \ldots, l_n^0 : \tau_n \rrbracket) &= \sum_{i=1}^{n} \text{size}(\tau_i) + 1 \\
\text{size}(\llbracket l_0^1 : \tau_1, \ldots, l_n^0 : \tau_n \rrbracket) &= \sum_{i=1}^{n} \text{size}(\tau_i) + 1 \\
\text{size}(\tau) &= 1 \text{ otherwise }
\end{align*}
\]
Lemma 18: The algorithmic subtyping terminates.

Proof: in all algorithmic subtyping rules, the sum of the sizes of the types in the subtyping judgments of the premises is strictly smaller than that of the conclusion. Also, the side conditions such as subclassing are decidable too.

Corollary 19: Subtyping is decidable. It is decidable to check whether \( \Theta; \Delta \vdash \tau_1 \leq \tau_2 \) holds.

Proof: by Lemmas 14, 16 and 18.

We will use the subtyping rules in Figure 7 and the algorithmic subtyping rules in Figure 14 interchangeably in the rest of the proof.

A.2.2 Minimal Typing

We design a set of algorithmic expression typing rules. Most rules are standard. Figure 15 lists non-standard rules. In a \texttt{c2r.tv}, to get the minimal typing of a record coerced from an object with type \( \alpha \), we need to find the least upper subclassing bound of \( \alpha \) that is a concrete class name, which is \( \alpha \uparrow \Delta \) (defined in Section A.1.1). In a \texttt{open} and a \texttt{open} \( \gg \), the minimal type of the expression \( e_2 \) might contain type variable \( \alpha \), whereas the minimal type of the open expression should not contain \( \alpha \). Therefore, we need to find the least subtyping bound of the minimal type of \( e_2 \), which is \( \tau \gg^\alpha \Delta \) (defined in Section A.1.2).

This new set of rules is syntax-directed. We prove that it is sound and complete with respect to the original expression typing rules.

Lemma 20: Minimal typing is sound. If \( \Theta; \Delta; \Sigma; \Gamma \vdash E : T \), then \( \Theta; \Delta; \Sigma; \Gamma \vdash E : T \).

Proof: by induction on algorithmic expression typing rules. Case \texttt{a.c2r.tv} \( E = c2r(e) \), \( T = \text{ApproxR}(\alpha, \alpha \uparrow \Delta) \) with subderivation \( \Theta; \Delta; \Sigma; \Gamma \vdash e : \alpha \).

By induction hypothesis, \( \Theta; \Delta; \Sigma; \Gamma \vdash e : \alpha \). By Lemma 9, \( \Theta; \Delta \vdash \alpha \ll \alpha \uparrow \Delta \) and \( \alpha \uparrow \Delta \) is a concrete class name. By \texttt{c2r.tv} \( \Theta; \Delta; \Sigma; \Gamma \vdash E : T \).

Case \texttt{a.open} \( E = \text{open}(e_1) \) in \( e_2 \), \( T = (\tau') \gg^\alpha \Delta, \alpha \ll \tau_a \) with subderivations \( \Theta; \Delta; \Sigma; \Gamma \vdash e_1 : \exists \beta \ll \tau_a, \tau, \Theta; \Delta, \alpha \ll \tau_a, \Sigma; \Gamma, x : \tau[\alpha/\beta] \vdash e_2 : \tau' \) (\( \alpha \notin \text{domain}(\Delta) \)).
Lemma 21

\[ \Theta; \Delta; \Sigma; \Gamma \vdash e : \alpha \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash c2r(e) : \text{ApproxR}(\alpha, \alpha \uparrow\Delta) \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash e_1 : \exists \beta \ll \tau_u. \tau \quad \alpha \notin \text{domain}(\Delta) \]

\[ \Theta; \Delta, \alpha \ll \tau_u; \Sigma; \Gamma \vdash \tau[\alpha/\beta] = e_2 : \tau' \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash (\alpha, x) = \text{open}(e_1) \text{ in } e_2 : (\tau') \uparrow_{\Delta, \alpha \ll \tau_u} \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash e_1 : \exists \beta \gg \tau_u. \tau \quad \alpha \notin \text{domain}(\Delta) \]

\[ \Theta; \Delta, \alpha \gg \tau_u; \Sigma; \Gamma \vdash \tau[\alpha/\beta] = e_2 : \tau' \]

\[ \Theta; \Delta; \Sigma; \Gamma \vdash (\alpha, x) = \text{open}(e_1) \text{ in } e_2 : (\tau') \uparrow_{\Delta, \alpha \gg \tau_u} \]

By induction hypothesis, \( \Theta; \Delta; \Sigma; \Gamma \vdash e_1 : \exists \beta \ll \tau_u. \tau \) and \( \Theta; \Delta, \alpha \ll \tau_u; \Sigma; \Gamma \vdash \tau[\alpha/\beta] \vdash e_2 : \tau' \). By properties of type lifting Lemma 11, \( \Theta; \Delta, \alpha \ll \tau_u \vdash e_2 : \tau \). By \text{sub} we have \( \Theta; \Delta, \alpha \ll \tau_u; \Sigma; \Gamma \vdash \tau[\alpha/\beta] \vdash e_2 : T \). By the definition of type lifting, \( \alpha \notin \text{free}(T) \). Therefore, \( \Theta; \Delta; \Sigma; \Gamma \vdash E : T \) by open.

Lemma 22

**Inversion of Subtyping**

- If \( \Theta; \Delta \vdash s \leq \{l_{1}^{\phi_1} : \tau_1, \ldots, l_{n}^{\phi_n} : \tau_n\} \), then either \( s = \{l_{1}^{\phi_1} : \tau_1', \ldots, l_{n}^{\phi_n} : \tau_n'\} \) or \( s = \{l_{1}^{\phi_1} : \tau_1, \ldots, l_{n}^{\phi_n} : \tau_n\} \). In either case \( \Theta; \Delta \vdash t_i \leq t_i' \forall \phi_i = 1, \) and \( t_i' = t_i \forall \phi_i = M. \)
- If \( \Theta; \Delta \vdash s \leq \{l_{1}^{\phi_1} : \tau_1, \ldots, l_{n}^{\phi_n} : \tau_n\} \), then \( s = \{l_{1}^{\phi_1} : \tau_1, \ldots, l_{n}^{\phi_n} : \tau_n\} \).
- If \( \Theta; \Delta \vdash s \leq \text{array}(\tau) \), then \( s = \text{array}(\tau) \).
- If \( \Theta; \Delta \vdash s \leq \text{int} \), then \( s = \text{int} \).
- If \( \Theta; \Delta \vdash S \leq \forall \alpha_1 < u_1, \ldots, u_m. (\tau_1, \ldots, \tau_n) \rightarrow \tau \), then (1) \( S = \forall \alpha_1 < u_1', \ldots, u_m. (\tau_1', \ldots, \tau_n') \rightarrow \tau \), (2) \( \Theta; \Delta, \alpha_1 < \text{Topc}, \mu \ll \text{Topc} \vdash t_i \leq s \forall 1 \leq i \leq n \), (3) \( \Theta; \Delta, \alpha_1 < \text{Topc}, \mu \ll \text{Topc} \vdash s \leq \tau \), and (4) if \( \exists \tau_1, \ldots, \tau_m \) such that \( \forall 1 \leq i \leq n \), \( \Theta; \Delta \vdash t_i \leq u_i[t_1, t_m/\alpha_1, \ldots, \alpha_m] \), then \( \forall 1 \leq i \leq m \), \( \Theta; \Delta \vdash t_i \leq u_i[t_1, \ldots, t_m/\alpha_1, \ldots, \alpha_m] \).
- If \( \Theta; \Delta \vdash s \leq \exists \alpha < \tau_1, \tau_2 \), then \( s = \exists \alpha < \tau_1, s_2 \), \( \Theta; \Delta \vdash s \leq \tau_1, \tau_2 \), \( \Theta; \Delta \vdash s \leq \tau_1, s_2 \), \( \Theta; \Delta \vdash s \leq \tau_1 < s_1 \), and \( \Theta; \Delta, \alpha < \text{Topc} \vdash s_2 \leq \tau_2 \).
- If \( \Theta; \Delta \vdash s \leq \exists \alpha \gg \tau_1, \tau_2 \), then \( s = \exists \alpha \gg \tau_1, s_2 \), \( \Theta; \Delta \vdash s \leq \tau_1 < s_1 \), and \( \Theta; \Delta, \alpha < \text{Topc} \vdash s_2 \leq \tau_2 \).
- If \( \Theta; \Delta \vdash s \leq \text{Tag}(\tau) \), then \( s = \text{Tag}(\tau) \).
- If \( \Theta; \Delta \vdash s \leq \tau \) and \( \Theta; \Delta \vdash \tau : \Omega_c \), then \( s = \tau \).
- If \( \Theta; \Delta \vdash s \leq \text{Inty}(\tau_1, \tau_2) \), then \( s = \text{Inty}(\tau_1, \tau_2) \).

Proof: by inspection of algorithmic subtyping rules.

Lemma 23

**Minimal Typing is Complete**

If \( \Theta; \Delta; \Sigma; \Gamma \vdash E : T \), then \( \exists T_m \) such that \( \Theta; \Delta; \Sigma; \Gamma \vdash E : T_m \) and \( \Theta; \Delta \vdash T_m \leq T \).

Proof: by induction on the expression typing rules.

We define the size of expressions in Figure 16.

Lemma 24

**Minimal Typing terminates.**

Proof: in each inference rule, the premises refer to only subexpressions of the expression in the conclusion. The size of the expression in the conclusion is always larger than the sum of the subexpression sizes in the premises. Also the size conditions are decidable.
Lemma 27 Inversion of Values

\[ \delta = ron \text{ environment.} \]

Lemma 26 It preserves typing to substitute an appropriate type for the first type variable in the kind environment. If \( \Theta; \Delta; \Sigma; \Gamma \vdash e : \tau \) holds, we can first get the minimal type \( \tau_m \) of \( e \) such that \( \Theta; \Delta; \Sigma; \Gamma \vdash e : \tau_m \), then test whether \( \Theta; \Delta \vdash \tau_m \leq \tau \). Because both minimal typing and subtyping are decidable, type checking is decidable.

A.3 Soundness

A.3.1 Substitution

Lemma 26 It preserves typing to substitute an appropriate type for the first type variable in the kind environment. If \( \Theta; \Delta; \Sigma; \Gamma \vdash E : T \), \( \Delta = \eta \ll \tau, \Delta' \) and \( \Theta; \bullet \vdash s \ll \tau \) (or \( \Delta = \eta \gg \tau, \Delta' \) and \( \Theta; \bullet \vdash \tau \ll s \)), and \( \delta = s/\eta \), then \( \Theta; \Delta'[\delta]; \Sigma[\delta]; \Gamma[\delta] \vdash E[\delta] : T[\delta] \).

Proof: by induction on expression typing rules.

A.3.2 Preservation

Lemma 27 Inversion of Values

- If \( H(\ell) = \{ k_1 = v_1, \ldots, k_m = v_m \} \) and \( \Theta; \bullet; \Sigma; \Gamma \vdash \ell : \{ t_1^{\alpha_1}, \ldots, t_n^{\alpha_n} : \tau_n \} \), then \( m \geq n \), \( k_i = l_i \) and \( \Theta; \bullet; \Sigma; \Gamma \vdash v_i : \tau_i \ \forall i \leq n \).
- If \( H(\ell) = \{ v_0, \ldots, v_{n-1} \} \) and \( \Theta; \bullet; \Sigma; \Gamma \vdash \ell : \text{array}(\tau') \), then \( \tau' = \tau \) and \( \Theta; \bullet; \Sigma; \Gamma \vdash \ell : \tau \ \forall 0 \leq i \leq n - 1 \).
- If \( \Theta; \bullet; \Sigma; \Gamma \vdash \ell : \forall \alpha_1 < u_1, \ldots, \alpha_m < u_m. (\tau_1, \ldots, \tau_n) \rightarrow \tau \) and \( \Sigma(\ell) = \text{fun} < \alpha_1 < u_1', \ldots, \alpha_m < u_m' > (x_1 : s_1, \ldots, x_n : s_n) : s = e_0 \), then (1) let \( \tau_f = \forall \alpha_1 < u_1', \ldots, \alpha_m < u_m'. (\tau_1, \ldots, \tau_n) \rightarrow \tau \) and \( \tau_f = \forall \alpha_1 < u_1', \ldots, \alpha_m < u_m'. (s_1, \ldots, s_n) \rightarrow s \), then \( \Sigma(\ell) = \tau_f' \) and \( \Theta; \bullet \vdash \tau_f' \leq \tau_f \). (2) \( \Theta; \bullet; \Sigma; \Gamma \vdash \ell : t_f' ; x_1 : s_1, \ldots, x_n : s_n ; e_0 : s \).
- If \( \Theta; \bullet; \Sigma; \Gamma \vdash v : \exists \beta < \tau_u. \tau \) and \( v = \text{pack} s_0 \) as \( \beta < s_u \) in \( (v' : s) \), then \( \Theta; \bullet \vdash s_0 < s_u, \Theta; \bullet \vdash s_u < \tau_u, \Theta; \beta \ll \text{Topic} \vdash s \leq \tau, \) and \( \Theta; \bullet; \Sigma; \Gamma \vdash v' : s[s_0/\beta] \).
• If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \exists \beta \Rightarrow_{u. \tau}$ and $v = \text{pack} s_0$ as $\beta \Rightarrow s_u$ in $(v' : s)$, then $\Theta;\bullet; s_u \ll s_0$, $\Theta;\bullet; \tau_u \ll s_u$, $\Theta;\beta \ll \text{Topc}\vdash s \leq \tau$, and $\Theta;\bullet;\Sigma;\Gamma \vdash v' : s[s_0/\beta]$.

• If $v = \text{tag}(C)$ and $\Theta;\bullet;\Sigma;\Gamma \vdash v : \text{Tag}(\tau)$, then $\tau = C$.

• If $\Theta;\bullet;\Sigma;\Gamma \vdash C(v) : C'$ then $C = C'$ and $\Theta;\bullet;\Sigma;\Gamma \vdash v : R(C)$.

• If $\Theta;\bullet;\Sigma;\Gamma \vdash r2\text{im}[I,C](v) : \text{Inty}(I',C')$ then $I = I'$, $C = C'$ and $\Theta;\bullet;\Sigma;\Gamma \vdash v : R(I,C)$.

**Definition 28** Extension of Environments. $\Sigma'$ extends $\Sigma$ means that $\Sigma' = \Sigma, \Sigma_{\text{new}}$ for some $\Sigma_{\text{new}}$ such that $\text{dom}(\Sigma') \cap \text{dom}(\Sigma_{\text{new}}) = \emptyset$. Similarly, $\Gamma'$ extends $\Gamma$ means $\Gamma' = \Gamma, \Gamma_{\text{new}}$ for some $\Gamma_{\text{new}}$ such that $\text{dom}(\Gamma') \cap \text{dom}(\Gamma_{\text{new}}) = \emptyset$.

**Theorem 29** Evaluation of ECI expressions preserves types. If

1. $\text{freetvs}(\Sigma) = \emptyset$ \quad $\Theta \vdash H : \Sigma$ \quad $\Theta;\Sigma \vdash V : \Gamma$
2. $\Theta;\Sigma;\Gamma \vdash E : T$
3. $(H;V;E) \mapsto (H';V';E')$

then $\exists \Sigma'$ and $\Gamma'$ such that

1. $\text{freetvs}(\Sigma') = \emptyset$ \quad $\Theta \vdash H' : \Sigma'$ \quad $\Theta;\Sigma' \vdash V' : \Gamma'$
2. $\Theta;\Sigma;\Gamma \vdash E' : T$
3. $\Sigma'$ extends $\Sigma$ and $\Gamma'$ extends $\Gamma$.

Proof: by induction on expression typing rules.

**Corollary 30** (Preservation) If $\Sigma \vdash P : \tau$ and $P \mapsto P'$, then $\exists \Sigma'$ such that $\Sigma' \vdash P' : \tau$.

**A.3.3 Progress**

**Lemma 31** Canonical forms

1. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \{l_1^{\phi_1} : \tau_1, \ldots, l_n^{\phi_n} : \tau_n\}$ and $\Theta \vdash H : \Sigma$, then $v$ is a label and $H(v) = \{l_1 = v_1, \ldots, l_n = v_n, \ldots\}$.
2. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \text{array}(\tau)$ and $\Theta \vdash H : \Sigma$, then $v$ is a label and $H(v) = [v_0, \ldots, v_{n-1}]^\tau$.
3. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \forall \text{tv}s(\tau_1, \ldots, \tau_n) \rightarrow \tau$ $(\text{tv}s = \alpha_1 \ll u_1, \ldots, \alpha_m \ll u_m)$ and $\Theta \vdash H : \Sigma$, then $v$ is a label and $H(v) = \text{fix } g(\text{tv}s')(x_1 : \tau_1', \ldots, x_n : \tau_n') : \tau' = e_m$ and $\text{tv}s' = \alpha_1 \ll u_1', \ldots, \alpha_m \ll u_m$.\[\]
4. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \exists \alpha \ll \tau_u.\tau$, then $v = \text{pack} \tau_0$ as $\alpha \ll \tau_u$ in $(v' : \tau')$.
5. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \exists \alpha \gg \tau_u.\tau$, then $v = \text{pack} \tau_0$ as $\alpha \gg \tau_u$ in $(v' : \tau')$.
6. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \text{Tag}(\tau)$, then $v = \text{tag}(C)$ for some $C$.
7. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \text{Tag}(C)$, then $v = \text{tag}(C)$.
8. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : C$, then $v = C(v')$ for some value $v'$.
9. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \text{Inty}(I,\tau)$, then $v = \text{r2im}[I,C](v')$ for some value $v'$ and class $C$.
10. If $\Theta;\bullet;\Sigma;\Gamma \vdash v : \text{int}$, then $v$ is an integer.

**Theorem 32** If $\text{freetvs}(\Sigma) = \emptyset$, and $\Theta \vdash H : \Sigma$, and $\Theta;\Sigma \vdash V : \Gamma$ and $\Theta;\bullet;\Sigma;\Gamma \vdash E : T$, then either $E$ is a value, or $E$ can evaluate one step, that is, $\exists H', V'$ and $E'$ such that $(H;V;E) \mapsto (H';V';E')$.\[\]
Proof: by induction on expression typing rules.

**Corollary 33 (progress)** If $\Sigma \vdash P : \tau$, then either the main expression in $P$ is a value, or $\exists P'$ such that $P \rightarrow P'$.

**Theorem 34** ECI is Sound. Well-typed ECI programs do not get stuck.

Proof: by progress and preservation.

### B The Source Language

This section describes the source language and formalizes the translation from the source language to ECI. Figure 17 shows the syntax of the source language.

**Figure 17:** Syntax of the Source Language

```
\begin{align*}
\tau & := \text{int} | C | I \mid \text{array}(C) \\
e & := n \mid \ell \mid x \mid x : \tau = e_1 \text{ in } e_2 \mid x := e_1 \text{ in } e_2 \mid \text{new } C \{ f_1 = e_1, \ldots, f_n = e_n \} \mid e.f_i \\
& \quad \mid e_1.f_i := e_2 \text{ in } e_3 \mid e.m(e_1, \ldots, e_n) \mid \text{imthd}[I.m](e_1, \ldots, e_n) \\
& \quad \mid \text{new}[e_0, \ldots, e_{n-1}]^n \mid e_1[e_2] := e_3 \text{ in } e_4 \mid e_1[e_2] \mid \text{len}(e) \mid \text{cast}[C](e) \mid \text{cast}[I](e) \\
v & := n \mid \ell \\
hv & := C \{ f_1 = v_1, \ldots, f_n = v_n \} \mid [v_0, \ldots, v_{n-1}]^n \\
mdecl & := \tau \ m(x_1 : \tau_1, \ldots, x_n : \tau_n) = e \\
msig & := \tau \ m(x_1 : \tau_1, \ldots, x_n : \tau_n) \\
idecl & := I : J_1, \ldots, J_n \{ \msig_{1}, \ldots, \msig_{k} \} \\
cdecl & := C : B, I_1, \ldots, I_p \{ f_1 : \tau_1, \ldots, f_n : \tau_n, mdecl_1, \ldots, mdecl_k \} \\
dcl & := cdecl | idecl \\
prog & := dcl_1, \ldots, dcl_n \text{ in } e
\end{align*}
```

The source language is roughly Featherweight Java (FJ) [13] enhanced with interfaces, assignments, and arrays. To simplify the representation, we use only one dimensional arrays of objects. The source language can support more general arrays with simple extensions. All local variables and record fields are mutable. Variables are renamed such that no two variables have the same name. A “new” expression is used to create objects instead of constructors as in FJ. Expression “imthd[I.m](e_1, \ldots, e_n)” invokes an interface method $m$ (in interface $I$) on $e$ with arguments $e_1, \ldots, e_n$. Interface cast expression $\text{cast}[I](e)$ casts an expression $e$ to interface $I$. An interface declaration contains a sequence of superinterfaces and a sequence of method signatures. For simplicity, the source language requires that methods declared in each interface be different from those in the superinterfaces. The semantics of the source language is straightforward.

### B.1 Semantics of the Source Language

Figures 18–23 show the semantics of the source language.

As shown in Figure 18, the source language has covariant arrays and does not separate subtyping from subtyping.

Figure 19 defines helper functions used for type checking source language programs. Suppose $\overrightarrow{F}$ is a set of field declarations, $\overrightarrow{M}$ is a set of method declarations, and $\overrightarrow{MS}$ is a set of method signatures. The function $\text{fields}(\Theta, C)$ returns all $C$’s fields, including those from superclasses. The function $\text{mtype}(\Theta, m, C)$ returns the type of method $m$ in class $C$. The function $\text{mbody}(\Theta, m, C)$ returns the implementations of method $m$ in class $C$. If $C$ has a declaration for $m$, $\text{mtype}$ and $\text{mbody}$ return the type and implementation for $m$ respectively. Otherwise, they look in $C$’s superclass. When applied to an interface $I$, $\text{mtype}(\Theta, m, I)$ returns the types of $m$ in $I$.

Figure 20 defines well-formedness of methods, interface declarations, class declarations, and programs. Note that when type checking a method, we need to know the “this” pointer type. The methods declared in
\[
\Theta(I) = I : J_1, \ldots, J_n \quad 1 \leq i \leq n \\
\Theta \vdash I \leq J_i
\]

\[
\Theta(C) = C : B, I_1, \ldots, I_p \{\ldots\} \\
\tau = B \lor I_j \forall 1 \leq j \leq p
\]

\[
\Theta \vdash I \leq J
\]

\[
\Theta \vdash \tau \leq \tau
\]

\[
\Theta \vdash \tau_1 \leq \tau_2 \\
\Theta \vdash \text{array}(\tau_1) \leq \text{array}(\tau_2)
\]

\[
\Theta \vdash \tau \leq \tau
\]

\[
\Theta \vdash \tau_1 \leq \tau_2 \quad \Theta \vdash \tau_2 \leq \tau_3
\]

Figure 18: Subtyping of the Source Language

\[
\Theta(C) = C : B, I_1, \ldots, I_p \{\overline{F}, \overline{M}\}
\]

\[
\text{fields}(\Theta, C) = \text{fields}(\Theta, B), \overline{F}
\]

\[
\begin{align*}
\Theta(C) &= C : B, I_1, \ldots, I_p \{\overline{F}, \overline{M}\} \\
\tau(x_1 : \tau_1, \ldots, x_n : \tau_n) &= e \in \overline{M}
\end{align*}
\]

\[
\begin{align*}
\text{mtype}(\Theta, m, C) &= (\tau_1, \ldots, \tau_n) \rightarrow \tau \\
\text{mbody}(\Theta, m, C) &= \tau m(x_1 : \tau_1, \ldots, x_n : \tau_n) = e
\end{align*}
\]

\[
\Theta(C) = C : B, I_1, \ldots, I_p \{\overline{F}, \overline{M}\} \\
m \text{ is not declared in any of } \overline{M}
\]

\[
\begin{align*}
\text{mtype}(\Theta, m, C) &= \text{mtype}(\Theta, m, B) \\
\text{mbody}(\Theta, m, C) &= \text{mbody}(\Theta, m, B)
\end{align*}
\]

\[
\Theta(I) = I : [\overline{MS}] \\
\tau m(x_1 : \tau_1, \ldots, x_n : \tau_n) \in \overline{MS}
\]

\[
\begin{align*}
\text{mtype}(\Theta, m, I) &= (\tau_1, \ldots, \tau_n) \rightarrow \tau \\
\Theta(I) &= I_1, \ldots, I_n \{\ldots\} \\
\exists 1 \leq j \leq n \text{ mtype}(\Theta, m, I_j) &= (\tau_1, \ldots, \tau_n) \rightarrow \tau
\end{align*}
\]

\[
\begin{align*}
\text{mtype}(\Theta, m, I) &= (\tau_1, \ldots, \tau_n) \rightarrow \tau
\end{align*}
\]

Figure 19: Helper Functions for the Source Language Typing

an interface should be distinct from those in the superinterfaces. Similarly, fields declared in a class should be distinct from those in the superclass. Method overriding requires method types be the same.

Figure 21 shows typing rules for heap values. There are only two kinds of heap values: objects and arrays. An object of \(C\) is required to specify all fields of \(C\) including those in the superclasses to simplify field fetch.

Figure 22 shows typing rules for expressions. All rules are straightforward.

Figure 23 shows the evaluation rules.

### B.2 Translation from the Source to ECI

The source-ECI translation performs several tasks, besides lowering types and expressions. First, it collects members for each class and each interface, including those from superclasses or superinterfaces. Second, it lifts method definitions to global functions, after adding the “this” parameter. Therefore after translation, class declarations have only method signatures, not method bodies. Third, it creates itables and vtables for classes.

**Type Translation** Class and interface names are translated to existential types. Covariant array types are translated to existential types that hide the actual element types. The type translation is shown as follows:

\[
\begin{align*}
|\text{int}| &= \text{int} \\
|\tau| &= \exists \alpha \ll \tau. \alpha \\
|\text{array}(C)| &= \exists \alpha \ll C. \{\text{tag} : \text{Tag}(\alpha), \text{table} : \text{array}(\exists \beta \ll \alpha. \beta)\}
\end{align*}
\]

\[
\tau = C \lor I
\]

22
\[
mbody(\Theta, m, C) = (\tau \ m(x_1 : \tau_1, \ldots, x_n : \tau_n) = e) \\
\Theta; \cdot; this : C, x_1 : \tau_1, \ldots, x_n : \tau_n \vdash e : \tau \\
\Theta \vdash (C, \tau \ m(x_1 : \tau_1, \ldots, x_n : \tau_n) = e)
\]

\(\forall 1 \leq i \leq p, I_i\) declared before \(I\), \(\Theta \vdash I_i\), and \(\forall 1 \leq q \leq k, m\text{type}_q \notin m\text{closure}(I_i)\)

\(\Theta \vdash I : I_1, \ldots, I_p\{m\text{sig}_1, \ldots, m\text{sig}_k\}\)

If \(m\text{decl}_i\) overrides a method \(m\) in \(B\), then \(m\text{type}(\Theta, m, C) = m\text{type}(\Theta, m, B)\)

\(\forall 1 \leq i \leq p, \Theta \vdash I_i : \{\_\}, \forall m \in m\text{closure}(I_i), m\text{type}(\Theta, m, C) = m\text{type}(\Theta, m, I_i)\)

\(\Theta \vdash C : B, I_1, \ldots, I_p\{f_1 : \tau_1, \ldots, f_n : \tau_n, m\text{decl}_1, \ldots, m\text{decl}_k\}\)

\(\text{fields}(\Theta; C) = f_1 : \tau_1, \ldots, f_n : \tau_n\)

\(\Theta; \Sigma; \Gamma \vdash v_i : \tau_i \ \forall 1 \leq i \leq n\)

\(\Theta; \Sigma; \Gamma \vdash C\{f_1 = v_1, \ldots, f_n = v_n\} : C\)

\(\Theta; \Sigma; \Gamma \vdash [v_0, \ldots, v_{n-1}]^\tau : \text{array}(\tau)\)

\(\text{method translation}\) A method declaration is translated to a pair of a function label and a global function definition with an explicit “this”. The translation of a method needs the enclosing class name to specify the “this” pointer’s type. Suppose class \(C\) implements a method \(m\). The translation generates a new label \(l_m\) and translates the method as follows:

\(|\tau \ m(x_1 : \tau_1, \ldots, x_n : \tau_n) = e, C| =\)

\[
(l_m, \text{fix } m\langle \rangle (\text{this } : \exists \alpha \ll C. \alpha, x_1 : |\tau_1|, \ldots, x_n : |\tau_n|) : |\tau| = |e|)
\]

A method signature in the source language is translated to an ECI method declaration:

\(|\tau \ m(x_1 : \tau_1, \ldots, x_n : \tau_n)| = m : (|\tau_1|, \ldots, |\tau_n|) |\tau|

\(\text{expression translation}\) Figure 24 shows the translation of expressions. Each new variable introduced during translation is unique. The translation of expression \(\text{new } C\{f_i = e_i\}_{i=1}^n\) creates a record with \(\text{vtable}_C\) (vtable of \(C\)) and fields \(f_1, \ldots, f_n\) and then coerces the record to an object. Field fetch and method invocation first open the object and then coerce the opened object to a record.

The translation of interface method invocation “\(\text{imthd}[I.m][e(e_1, \ldots, e_n)]\)” uses the “\(\text{ILookup}\)” function defined in Section 2 to find the method table for \(I\), and then coerces the abstract method table to a concrete one and fetches the method \(m\).

The translation of array creation packs the tag of the element type along with the element array to the desired existential type. The translation of array store instructions inserts store checks: the object to be stored is first cast to the target element type.

The translation of the two cast expressions “\(\text{cast}[C](e)\)” and “\(\text{cast}[I](e)\)” calls the polymorphic functions “\(\text{Downcast}\)” and “\(\text{InterfaceCast}\)” with appropriate type arguments.

\(\text{interface translation}\) A source interface declaration is translated to an ECI interface declaration. The translation collects all super interfaces and all methods including those in the super interfaces. Function \(m\text{closure}\) computes all the superinterfaces of a class or an interface. Definitions of \(m\text{closure}\) on classes are in
\[
\begin{array}{l}
\Theta; \Sigma; \Gamma \vdash n : \text{int} \quad \Theta; \Sigma; \Gamma \vdash x : \Gamma(x) \quad \Theta; \Sigma; \Gamma \vdash \ell : \Sigma(\ell) \\
\Theta; \Sigma; \Gamma \vdash e : \tau \\ 
\end{array}
\]

\[
\begin{array}{l}
\Theta; \Sigma; \Gamma \vdash e_1 : \tau \quad \Theta; \Sigma; \Gamma, x : \tau \vdash e_2 : \tau' \\
\Theta; \Sigma; \Gamma \vdash x : \tau = e_1 \text{ in } e_2 : \tau' \\
\Theta; \Sigma; \Gamma \vdash e_1 : \Gamma(x) \quad \Theta; \Sigma; \Gamma \vdash e_2 : \tau \\
\Theta; \Sigma; \Gamma \vdash x := e_1 \text{ in } e_2 : \tau \\
\end{array}
\]

\[
\begin{array}{l}
\text{fields}(\Theta, C) = f_1 : \tau_1, \ldots, f_n : \tau_n \\
\Theta; \Sigma; \Gamma \vdash e_1 : \tau_i \quad \forall 1 \leq i \leq n \\
\Theta; \Sigma; \Gamma \vdash \text{new } C\{f_1 = e_1, \ldots, f_n = e_n\} : C \\
\Theta; \Sigma; \Gamma \vdash e_1 : C \\
\text{fields}(\Theta, C) = f_1 : \tau_1, \ldots, f_n : \tau_n \\
1 \leq i \leq n \\
\Theta; \Sigma; \Gamma \vdash e_2 : \tau_i \\
\Theta; \Sigma; \Gamma \vdash e_3 : \tau \\
\Theta; \Sigma; \Gamma \vdash e_1.f_i := e_2 \text{ in } e_3 : \tau \\
\Theta; \Sigma; \Gamma \vdash e : C \\
\text{mtype}(\Theta, m, C) = (\tau_1, \ldots, \tau_n) \rightarrow \tau \\
\Theta; \Sigma; \Gamma \vdash e_i : \tau_i \quad \forall 1 \leq i \leq n \\
\Theta; \Sigma; \Gamma \vdash e : \text{m}(e_1, \ldots, e_n) : \tau \\
\Theta; \Sigma; \Gamma \vdash e_1 : \tau_i \quad \forall 0 \leq i \leq n - 1 \\
\Theta; \Sigma; \Gamma \vdash \text{new}[e_0, \ldots, e_{n-1}]^\tau : \text{array}(\tau) \\
\Theta; \Sigma; \Gamma \vdash e_1 : \text{array}(\tau) \\
\Theta; \Sigma; \Gamma \vdash e_2 : \text{int} \\
\Theta; \Sigma; \Gamma \vdash e_1[e_2] : \tau \\
\Theta; \Sigma; \Gamma \vdash e_1 : \text{array}(\tau) \\
\Theta; \Sigma; \Gamma \vdash e_2 : \text{int} \\
\Theta; \Sigma; \Gamma \vdash e_3 : \tau \\
\Theta; \Sigma; \Gamma \vdash e_4 : \tau' \\
\Theta; \Sigma; \Gamma \vdash e_1[e_2] := e_3 \text{ in } e_4 : \tau' \\
\Theta; \Sigma; \Gamma \vdash \text{mtype}(\Theta, m, I) = (\tau_1, \ldots, \tau_n) \rightarrow \tau \\
\Theta; \Sigma; \Gamma \vdash e_i : \tau_i \quad \forall 1 \leq i \leq n \\
\Theta; \Sigma; \Gamma \vdash \text{imthd}[I.m][e(e_1, \ldots, e_n)] : \tau \\

Figure 24: Translation of Expressions

25
the explanation of class declaration translation. Function \textit{mclosure} computes all the methods in an interface. Duplicated elements are removed after set union. Interface declarations are translated as follows:

\[
\text{mclosure}(I : I_1, \ldots, I_n \{ \}) = \text{mclosure}(I_1) \cup \ldots \cup \text{mclosure}(I_n) \cup \{ I_1, \ldots, I_n \} \\
\text{mclosure}(I : I_1, \ldots, I_n \{ \text{msig}_1, \ldots, \text{msig}_k \}) = \\
\text{mclosure}(I_1) \cup \ldots \cup \text{mclosure}(I_n) \cup \{ \text{msig}_1, \ldots, \text{msig}_k \}
\]

\[
\text{idcl} = I : J_1, \ldots, J_p \{ \text{msig}_1, \ldots, \text{msig}_q \} \\
\text{mclosure}(\text{idcl}) = \text{msig}'_1, \ldots, \text{msig}'_q
\]

\[
|\text{idcl}| = I : J_1', \ldots, J_p' \{ \text{mcdecl}'_1, \ldots, \text{mcdecl}'_q \}
\]

**Itable Entry Creation** When the translation creates the itable for class \( C \), it first creates an entry for each interface that \( C \) implements. Suppose \( C \) implements interface \( I \), the translation creates two heap values for \( I \): the first is a record labeled by \( l_{\text{itable}} \) for the method table, and the second is a record labeled by \( l_{\text{entry}} \) consisting of the interface tag and the method table. The itable entry for the interface is coerced from the second record. We use \( H(I,C) \) to represent the two heap values, and \( \text{entry}(I,C) \) for the itable entry. They are defined as follows:

\[
\text{mclosure}(I) = \text{msig}'_1, \ldots, \text{msig}'_q \text{ msig}'_i \text{ declares } m_i \forall 1 \leq i \leq q
\]

\[
\text{mcdecl}'_i \text{ defines } m_i \text{ in } C \mid \text{mcdecl}'_i, C[|l_{\text{mcdecl}}]\text{ }\forall 1 \leq i \leq q
\]

\[
H(I,C) = \left( l_{\text{itable}} \leadsto \{ m_1 = l_{m_1}, \ldots, m_q = l_{m_q} \}, \right. \\
\left. l_{\text{entry}} \leadsto \{ \text{tag} = \text{tag}(I), \text{itable} = r2m[I,C](l_{\text{itable}}) \} \right)
\]

\[
\text{entry}(I,C) = \text{pack } I \text{ as } \alpha \gg C \text{ in } (l_{\text{entry}} : \{ \text{tag} : \text{Tag}(I), \text{itable} = \text{itable}(I,C) \})
\]

**Class Translation** A class declaration in the source language is translated to a class declaration in ECI and a set of heap values. Suppose class \( C \) has a superclass \( B \) and \( B \) has been translated to a declaration in ECI with fields \( \text{fields}_B \) and methods \( \text{methods}_B \) and method implementations \( \text{vms}_B \) in the vtable. The method definitions in \( C \) \( \text{mdecl}_1, \ldots, \text{mdecl}_k \) are translated to functions \( \text{mbody}_1, \ldots, \text{mbody}_k \).

Methods for \( C \) (\text{methods}_C) consist of those in \( B \) (\text{methods}_B) and \( C \)'s methods \( m_1, \ldots, m_k \). Because of overriding, \( m_1, \ldots, m_k \) may override methods in \( \text{methods}_B \). We use operator \( \oplus \) for concatenation with masking: if \( S \) is a sequence of bindings, then \( S \oplus b \) appends \( b \) to \( S \) if \( S \) does not have the item bound in \( b \). Otherwise, \( S \oplus b \) replaces \( b \) with the corresponding entry in \( S \). Auxiliary function \( \text{mtype}(\Theta, m, C) \) returns the type of method \( m \) in class \( C \).

To create vtables of \( C \), we need to find all method implementations in \( C \) (\text{vms}_C). Again, we use \( \oplus \) to concatenate implementations in \( B \) \( \text{vms}_B \) with method definitions in \( C \).

The class declaration for \( C \) (\text{class}) includes all \( C \)'s super interfaces (\text{iclosure}(C)), fields in \( B \) (\text{fields}_B) and its new fields \( f_1, \ldots, f_n \), and \text{method}_C.

The translation of \( C \)'s declaration builds a set of heap values \( H_C \), which includes functions \( \text{mbody}_1, \ldots, \text{mbody}_k \), heap values for the superinterfaces \( I_1', \ldots, I_p' \), the itable \( \text{itable}_C \), and the vtable \( \text{vtable}_C \). The itable has an entry for each of the superinterfaces. The vtable is a record of \( C \)'s tag, the itable, and method implementations \( \text{vms}_C \).

The following rule shows the class translation:

\[
\text{iclosure}(C : B, I_1, \ldots, I_n \{ \}) = \\
\text{iclosure}(B) \cup \ldots \cup \text{iclosure}(I_n) \cup \{ I_1, \ldots, I_n \}
\]

\[
|B| = (B : \{ \text{fields}_B, \text{methods}_B \}, H_B) \\
H_B(\text{vtable}) = \{ \text{tag} = \_\text{itable} = \_\text{vms}_B \}
\]

\[
\text{mdecl}_i \text{ defines } m_i, \mid \text{mdecl}_i, C[|l_{\text{mdecl}}]\text{ }\forall 1 \leq i \leq k
\]

\[
\text{methods}_C = \text{methods}_B \oplus m_1 : \text{mtype}(\Theta, m_1, C) \oplus \ldots \oplus m_k : \text{mtype}(\Theta, m_k, C)
\]

\[
\text{vms}_C = \text{vms}_B \oplus m_1 = l_{m_1} \oplus \ldots \oplus m_k = l_{m_k} \mid \text{iclosure}(C) = I_1', \ldots, I_p'
\]

\[
\text{class} = C : B, I_1', \ldots, I_p' \{ \text{fields}_B, f_1 : \tau_1, \ldots, f_n : \tau_n, \text{methods}_C \}
\]

\[
H_C = \left( l_{m_1} \leadsto \text{mbody}_1, \ldots, l_{m_k} \leadsto \text{mbody}_k, H(I_1,C) \ldots, H(I_p,C), \right. \\
\left. \text{itable}_C \leadsto \{ \text{entry}(I_1,C) \ldots \text{entry}(I_p,C) \} \exists \alpha \gg C. \{ \text{tag} : \text{Tag}(\alpha), \text{itable} = \text{itable}_C, \text{vms}_C \} \right)
\]

\[
|C : B, \{ f_1 : \tau_1, \ldots, f_n : \tau_n, \text{mdecl}_1, \ldots, \text{mdecl}_k \} = (\text{class}, H_C)
\]
Program Translation. A program is translated to a set of new declarations, an initial heap (which contains function translated from method definitions, itables, and vtables), and a new main expression.

\[ \Theta = cdecl_1, \ldots, cdecl_m, idecl_1, \ldots, idecl_n \mid cdecl_i = (newcdecl_i, H_i) \forall 1 \leq i \leq m \]
\[ idecl_i = newidecl_i \forall 1 \leq i \leq n \quad H_0 = H_1, \ldots, H_m \]

\[ |\Theta|_e = (newcdecl_1, \ldots, newcdecl_m, newidecl_1, \ldots, newidecl_n; H_0; \bullet; |e|) \]

Next we prove that the translation from the source language to ECI preserves types.

Lemma 35 If \( \tau_1 \) and \( \tau_2 \) are class or interface names and \( \Theta \vdash \tau_1 \leq \tau_2 \) in the source language, then \( \Theta; \bullet \vdash \tau_1 \ll \tau_2 \) and \( \Theta; \bullet \vdash |\tau_1| \leq |\tau_2| \) in ECI.

Proof: by induction on source language subtyping rules.

In the rest of the section, we assume a source language program \( P = \Theta \) in \( e \), and \( |P| = (|\Theta|; H_0; \bullet; |e|) \), and \( |\Theta| \vdash H_0 : \Sigma_0 \) in ECI.

Lemma 36
- If \( fields(\Theta, C) = f_1 : \tau_1, \ldots, f_n : \tau_n \) in the source language, then \( |\Theta|(C) = \{ f_1 : |\tau_1|, \ldots, f_n : |\tau_n|, mdecls \} \).
- If \( mtype(\Theta, m, C) = (\tau_1, \ldots, \tau_n) \rightarrow \tau \) in the source language, then \( |\Theta|(C) = \{ \ldots; \{ m : (|\tau_1|, \ldots, |\tau_n|) \rightarrow |\tau| \} \ldots \} \).
- If \( mtype(\Theta, m, I) = (\tau_1, \ldots, \tau_n) \rightarrow \tau \) in the source language, then \( |\Theta|(I) = \{ \ldots; \{ m : (|\tau_1|, \ldots, |\tau_n|) \rightarrow |\tau| \} \ldots \} \).
- If \( \forall \text{ class } C \text{ in } \Theta, \text{ if } R(C) = \{ \{ \text{ vtable } : \text{ vtable}_C, \ldots \} \}, \text{ then } \Sigma_0(\text{ vtable}_C) = \text{ vtabletype}_C \).

Proof: the first three are proven by induction on the definition of \( fields(\Theta, C) \), \( mtype(\Theta, m, C) \) and \( mtype(\Theta, m, I) \) respectively. The last one is proven by induction on class declaration translation rules and by that method translation preserves types.

Lemma 37 The expression translation from the source language to ECI preserves types. If \( \Theta; \Sigma; \Gamma \vdash E : T \) in the source language, then \( |\Theta; \bullet; \Sigma_0; \Sigma; \Gamma| \vdash |E| : |T| \) in ECI, where \( |e_1| : \tau_1, \ldots, |\ell_n| : \tau_n = |\ell_1| : |\tau_1|, \ldots, |\ell_n| : |\tau_n| \), and \( |x_1| : \tau_1, \ldots, |x_m| : \tau_m = |x_1| : M \mid \tau_1, \ldots, |x_m| : M \mid \tau_m| \).

Proof: by induction over the expression typing rules in the source language.

C Extensions

ECI may be extended to support other interface implementation techniques.

CACAO used a table of itable pointers in the vtable [14]. Each interface has been assigned a unique offset in the table and thus can be accessed directly without runtime lookup. The table for type \( \tau \) can be represented as a record type in ECI \( \{ I_1 : \text{ Imty}(I_1, \tau), \ldots, I_n : \text{ Imty}(I_n, \tau) \} \).

The inline cache-based strategies cache one or more most recently invoked methods [12] and can be applied to interface method invocation. Method invocation is replaced with a stub that first compares the target method with the cached ones. If there is a match, the stub invokes the cached method. Otherwise, it resorts to the slow search. ECI may be extended with method tags, similar to class or interface tags, to model the method identities, and method tag comparison to refine types of methods.

Selector-based strategies assign unique ids (selectors) to identify method signatures [7, 11]. Each class contains a table of method pointers indexed by selectors. The table could be modeled by a record type in ECI, each field representing an interface method. Driesen used sparse arrays to reduce the space overhead for selector-indexed tables [9]. Unused space in the table of one class may contain method pointers for other classes. The type system of ECI could ignore the method pointers for other classes by using record subtyping to view the table as containing only methods for the current class. Graph-coloring [8] can assign the same selector to two different method signatures if the two methods are never implemented by the same class. To model this, ECI need to assign different types to the selector, depending on the class the selector is for.

Alpern et al. improved selector coloring by allowing color collisions [1]. If a collision occurs, a stub compares the target interface signature with those that share the same color to find out the right method pointer. This strategy could be modeled in ECI similarly to the inline cache-based one, by selector comparison.
